To help Canadian decision-makers as they respond to unprecedented challenges related to the COVID-19 pandemic, COVID-END in Canada is preparing rapid evidence responses like this one. The development and continued updating of this living evidence synthesis has been funded by the Canadian Institutes of Health Research (CIHR) and the Public Health Agency of Canada. The opinions, results, and conclusions are those of the team that prepared the living evidence synthesis, and independent of the Government of Canada, CIHR and the Public Health Agency of Canada. No endorsement by the Government of Canada, CIHR or Public Health Agency of Canada is intended or should be inferred

Original report: 29 March 2023 (Update #4)

Corrected report: 29 December 2023 (Correction note: the original report for this update #4 had an error in the footnotes to Table 1 describing the reasoning for the certainty assessments. For males 5-11 years old (after dose 2) and females 12-17 and 18-29 years (after dose 3), the certainty about there being probably fewer than 20 cases of myocarditis per million was rated up for evidence that was highly consistent with findings of very low (i.e., zero or near-zero) incidences across multiple studies. We have added this footnote and revised the other footnote ordering accordingly (all other reasons remaining the same).

#### Context

This is the fourth update of a living evidence synthesis initiated in November 2021 available at COVID-END and published in BMJ<sup>1</sup>. This update continues to focus on evidence for priority age and risk groups, cases confirmed by medical record review, and myocarditis/myopericarditis or pericarditis reported separately rather than in combination. For the contextual question on biological mechanisms, the focus is on empirical evidence from studies of patients with myocarditis following COVID-19 vaccination.

Throughout the report below, green font indicates new data or changes to conclusions or certainty in the evidence since the last update.

#### **Key Messages**

- Adolescent and young adult males are likely at increased risk of myocarditis after an mRNA vaccination, though . the absolute risk is extremely low and is outweighed by the benefits of protection against COVID-19 conferred by vaccination. Evidence suggests that the risk of myocarditis after booster doses is low for 12 to 17 year old males not having experienced myocarditis from the first or second dose.
- In this update, we identified the possibility of higher incidence in females after a 2<sup>nd</sup> dose and 30-39 year-old males than previously reported. This may be due in part to an "infamy bias" from public media reporting on myocarditis after mRNA vaccination which may have increased reports of myocarditis or led to patients with less severe symptoms seeking care when they may not have otherwise.<sup>2</sup> The higher observed incidence in new evidence compared to earlier reports may also be driven by the higher rate of myocarditis after Moderna compared with Pfizer, especially in the 30-39 year old age group.
- Newer studies report higher incidence than previously, leading to reduced certainty in the incidence estimates of myocarditis after an mRNA vaccination in 12-17 year-old and 30-39 year old males after a 3rd dose. This may be

Canadian Institutes Instituts de recherche of Health Research en santé du Canada

driven by limitations in reporting in earlier studies (i.e., reliance on passive surveillance systems), and/or by the aforementioned "infamy bias"

- Our findings suggest that receiving Pfizer (compared to Moderna), getting homologous doses, and waiting more . than 27 days between dose 1 and dose 2 may be preferred, especially in younger males.
- At approximately 6 months follow-up, it appears that about 80% of patients have fully recovered in terms of their myocarditis symptoms. Positive late gadolinium enhancement findings may persist in a majority of patients, indicating some residual fibrosis. A notable proportion of patients may experience other problems, such as anxiety/depression, pain, or difficulties with usual activities, but low follow-up rates and the lack of control data limit this finding. One large case series in the US found few (6% of affected) individuals missed school or work in the 2 weeks before follow-up due to myocarditis.
- The available studies on biological mechanisms appear to suggest that a humoral immune response (with antigen-specific antibodies) is not a major contributor. The cellular immune response (T-cell/CD4) may play a central role in mRNA vaccine associated myocarditis. Furthermore, increased expression of HLA-DR and increased anti-IL-1RA activity are consistent with an autoimmune mechanism. Elevated levels of spike proteins have been identified in the plasma and in cardiomyocytes of patients with vaccine associated myocarditis. They are potential modulators of the immune response and have correlated with cardiac troponin T levels and cytokine mediated innate immune activation. Firm conclusions are limited due to diverse study designs and populations. When assessing findings, it is not clear whether observed differences (e.g., increases in CD4+ T cells, cytokines) between myocarditis cases vs. vaccinated controls reflect a causal pathological immune response or reactive adaptive responses to the myocardial inflammation. In the clinical setting, endomyocardial biopsy is infrequently performed in individuals with suspected myocarditis. Accordingly, there is limited tissue data upon which to draw mechanistic conclusions.

#### Search date

#### **Key Questions**

**KQ1**: What is the incidence of myocarditis and pericarditis following mRNA COVID-19 vaccination, by age, sex and dose, in i) people 0-4 years, 5-11 years, 12-17 years, 18-29 years ii) recipients of any age after any booster dose, and iii) individuals with prior history of myocarditis following mRNA COVID-19 vaccination? KQ2: Among individuals of a similar age and sex, are there risk or protective factors (e.g., pre-existing conditions [e.g. cardiac diseases, immunocompromise], previous SARS-CoV-2 infection [symptomatic or asymptomatic] or other viral infections, pharmacotherapies [e.g., hormones], type of vaccine product, length of vaccine dosing interval, vaccine combination for first vs second vs booster doses) for myocarditis and pericarditis following mRNA COVID-19 vaccination?

KQ3: What are the characteristics and short-term clinical course of myocarditis or pericarditis after COVID-19 vaccination in i) children <12 years, ii) recipients of any age after any booster dose, and iii) individuals with prior history of myocarditis following mRNA COVID-19 vaccination?

KQ4: Among individuals of a similar age and sex who experienced myocarditis or pericarditis after mRNA COVID-19 vaccination, what is the longer term (≥12 weeks) prognosis, and does this vary by patient or vaccine characteristics?

#### **Contextual Question**

CQ1: What evidence is there for the hypothesized mechanisms involved in myocarditis and pericarditis following vaccination with mRNA COVID-19 vaccines, and do they vary by group?

#### **Our Approach**

For study eligibility for each question, see Supplementary Table 1. A single reviewer completed screening and another verified 50% of exclusions, using a machine-learning program to prioritize records. For the key questions, a second reviewer verified all exclusions at full text and data extraction stages. Risk of bias assessments (for KQs 1 & 2) using modified Joanna Briggs Institute tools were also verified by a second reviewer. For KQs 1 and 2, certainty of evidence ratings were based on team consensus using GRADE. The observational evidence in KQ1 started at low certainty and we considered rating up for a relatively large magnitude in incidence or highly consistent and very low (i.e., zero or near-zero) incidences across multiple studies. In KQ2 evidence started at high certainty. In the plain-language conclusions, we have used "probably", "may" and "uncertain" to reflect our level of certainty in the evidence based on GRADE of moderate, low, or very low, respectively.

Canadian Institutes Instituts de recherche of Health Research en santé du Canada

For KQ1, excess incidence rates <20 per million were considered very rare. For KQ2, ratio measures ≥1.5 (e.g., odds ratio, relative risk) were considered clinically relevant (e.g., OR <1.5 shows "little-to-no association").

For CQ1, one reviewer extracted data on the study population(s), methods and findings as well as authors' conclusions. We wrote a narrative for each study and attempted to draw any inferences of findings across studies.

### **Findings**

Table 1 and Table 2 contain the Summary of Findings for KQs 1 and 2. Results for KQs 3 and 4 are presented in Table 3 and Tables 4A and 4B. Table 5 provides details on the studies investigating biological mechanisms in patients experiencing myocarditis following COVID-19 vaccination, as well as any control groups. Appendix 1 contains: eligibility criteria; study characteristics tables of the passive and active reporting systems/studies contributing to KQ1 and studies included for KQ2 and risk of bias assessments for studies for KQ1 & KQ2. Appendix 2 contains details of our synthesis methods.

58 studies were included in this update. We identified 17 new reports across all questions (KQ1=8<sup>3-10</sup>, KQ2=5<sup>5-8 10</sup>. KQ3=0, KQ4=3<sup>11-13</sup>, CQ1=6<sup>14-19</sup>). Findings from 40 of 83 studies in the previous synthesis were carried forward (KQ1=25<sup>20-44</sup>, KQ2=16<sup>22 23 26 31 32 36 42 44-52</sup>; KQ3=2<sup>30 43</sup>; KQ4=9<sup>24 38 53-59</sup>; CQ1=1<sup>60</sup>). Three studies with <12 weeks of follow-up<sup>20 34 61</sup> and six studies with N<10<sup>62-67</sup> previously included in KQ4 no longer met our updated eligibility criteria. A presentation to the American Committee on Immunization Practices<sup>68</sup> previously included in KQ4 was superseded by a peer-reviewed publication reporting more detailed data.<sup>12</sup> Thirty-four studies previously included in CQ1 on hypothesized mechanisms did not reported any empirical data and were therefore excluded from this update.69-102

## KQ1: Incidence

Mvocarditis after dose 2

- Overall, the evidence remained consistent with the previous updates.
- We identified 1 new report on myocarditis after primary series of Moderna or Pfizer in children 6 months to 4 years old. The incidence of myocarditis after vaccination with an mRNA vaccine may be fewer than 20 cases per million. (low certainty).
- We included no new reports in 5-11-year-old males and females. The incidence of myocarditis after vaccination with Pfizer is probably fewer than 20 cases per million in both groups (moderate certainty).
- We identified 2 new studies reporting on 12-17-year-old males and females. In males, we remain moderately certain about a higher incidence (range 13 to 390 cases per million) of myocarditis after vaccination with an mRNA vaccine (moderate certainty). Among 12-17-year-old females, we remain uncertain about the incidence of presenting with myocarditis after vaccination with an mRNA (very low certainty, range: 1 to 50 cases per million).
- We identified 2 new studies reporting on 18-29-year-old males and females. Among 18-29-year-old males, the incidence of myocarditis after vaccination with an mRNA vaccine is probably between 29 and 157 cases per million (moderate certainty). Among 18-29-year-old females, we remain uncertain about the incidence of presenting with myocarditis after vaccination with an mRNA vaccine (very low certainty, range: 2 to 37 cases per million).
- We identified 2 new studies reporting on 18-39-year-old males and females. Among 18-39-year-old males, the incidence of myocarditis after vaccination with an mRNA vaccine is probably between 8 and 104 cases per million (moderate certainty). Among females, we continue to have low certainty about the incidence of myocarditis after vaccination with an mRNA vaccine (may be fewer than 20 cases per million).

Myocarditis after monovalent booster doses

- We identified 4 new reports of myocarditis after a third dose of monovalent mRNA vaccine. .
- We identified 1 additional report on monovalent booster doses among 5-11-year-old males and females. Based on two reports with data only from one passive surveillance/spontaneous reporting source, we are uncertain about the incidence of myocarditis after vaccination with a third dose of mRNA vaccine for this age group (very low certainty).
- We identified 1 new study reporting on monovalent booster doses among 12-17-year-olds. Among 12-17-year-old males, we are now uncertain about the incidence of myocarditis after vaccination with a third dose of a monovalent mRNA vaccine because of increased inconsistency in reported incidence across studies (very low

arche

- We identified 2 new studies reporting on monovalent booster doses among 18-29-year-olds. Among 18-29-yearold males, we remain uncertain about the incidence of myocarditis after a third dose of a monovalent mRNA vaccine due to large inconsistency across studies (very low certainty, range: 4 to 113 cases per million). Among 18-29-year-old females, we now have increased certainty that the incidence of myocarditis after vaccination with a third dose of a monovalent mRNA vaccine is probably fewer than 20 cases per million (moderate certainty).
- We identified three 3 studies reporting on monovalent booster doses among 30-39-year-old males and females. Among 30-39-year-old males, we are now uncertain about the incidence of myocarditis after a third dose of a monovalent mRNA vaccine (very low certainty, range: 1 to 48 cases per million). Among 30-39-year-old females, we continue to have low certainty that the incidence of myocarditis after vaccination with a third dose of a monovalent mRNA vaccine may be fewer than 20 cases per million.
- We identified one new study reporting on monovalent booster doses among  $\geq$ 40-year-olds. We continue to conclude that among both  $\geq$ 40-year-old males and  $\geq$ 40-year-old females, the incidence of myocarditis after vaccination with a third dose of an mRNA vaccine may be fewer than 20 cases per million (low certainty for both).
- We identified no new studies reporting on myocarditis after a fourth dose of a monovalent mRNA vaccine. We remain uncertain about the incidence of myocarditis after vaccination with a fourth dose of a monovalent mRNA vaccine in ≥12-year-olds due to indirectness from reporting outcomes across age and sex groups, and from all evidence coming from a single study using only data from passive surveillance/spontaneous reporting.

Myocarditis after bivalent booster doses

- We now refer to any dose after dose 2 (or dose 3 for immunocompromised individuals) as "booster doses" . because of changes around the nomenclature being used to refer to COVID-19 vaccine dosing.
- We identified 3 reports on myocarditis after any booster dose of a bivalent mRNA vaccine. No two studies . reported on the same age and sex group.
- Among children 5-11 years old we are uncertain about the incidence of myocarditis after a booster dose of bivalent mRNA vaccine due to evidence from a single report using data from passive surveillance/spontaneous reporting (very low certainty).
- Among individuals ≥12 years old we are uncertain about the incidence of myocarditis after a booster dose of bivalent mRNA vaccine due to evidence a single report using data from passive surveillance/spontaneous reporting (very low certainty).
- Among males  $\geq$ 50 years old, we are uncertain about the incidence of myocarditis after a booster dose of bivalent . mRNA vaccine due to evidence from a single report (very low certainty).
- Among females ≥50 years old we are uncertain about the incidence of myocarditis after a booster dose of bivalent • mRNA vaccine due to evidence from a single report (very low certainty).

Pericarditis

- We identified no new studies reporting on 5-11-year-olds. Based on a single study only reporting across both • sexes, we are uncertain about the incidence of pericarditis after Pfizer vaccination in 5-11 year-old males and females (very low certainty for both males and females).
- We identified no new studies reporting on 12-17-year-olds. For both 12-17 year old males and females, the incidence of pericarditis after vaccination with dose 2 of an mRNA vaccine may be fewer than 20 cases per million (low certainty for both).
- We identified no new studies reporting 18-24-year-olds. For 18-24 year-old males we remain uncertain about the incidence of pericarditis after vaccination with dose 2 of an mRNA vaccine due to inconsistency in estimates across studies (very low certainty). For 18-24 year old females, we continue to conclude that the incidence of pericarditis after vaccination with dose 2 of an mRNA vaccine may be fewer than 20 cases per million (low certainty).
- We identified no new studies reporting on 25-39-year-olds. We continue to conclude that for 25-39y old males that . the incidence of pericarditis after vaccination with dose 2 of an mRNA vaccine may be fewer than 20 cases per million (low certainty). For 25-39-year-old females, we remain uncertain about the incidence of pericarditis after vaccination with dose 2 of an mRNA vaccine due to inconsistency across studies.
- We identified no new reports on pericarditis after any booster dose of a monovalent mRNA vaccine.
- We identified 2 new reports on pericarditis after any booster dose of a bivalent mRNA vaccine.

- Among individuals ≥12 years old we are uncertain about the incidence of pericarditis after a booster dose of bivalent mRNA vaccine due to evidence a single report using data from passive surveillance/spontaneous reporting (very low certainty).
- Among males  $\geq$ 50 years old, we are uncertain about the incidence of pericarditis after a booster dose of bivalent mRNA vaccine due to evidence from a single report (very low certainty).
- Among females ≥50 years old we are uncertain about the incidence of pericarditis after a booster dose of bivalent mRNA vaccine due to evidence from a single report (very low certainty).

### KQ2: Risk Factors

#### Context

In KQ2 we assessed relative differences in outcomes across subgroups. It is important to consider these relative results in the context of the KQ1 findings reporting on incidence. That is, the relative differences between subgroups in females and older age groups identified in the KQ2 findings should be given less weight in policy decision-making based on the very low-to-no incidence of myocarditis after mRNA vaccination in these groups.

#### **Myocarditis**

#### Moderna versus Pfizer, after dose 2

- We identified 1 new study reporting on Moderna versus Pfizer in children 6 months to 4 years old. Among individuals 6 months to 4 years old, the incidence of myocarditis may not differ following primary series vaccination with Moderna compared with Pfizer (low certainty)
- We identified no new studies reporting on 12-17-year-old males and females. Among 12-17-year-old males, there may be a higher incidence of myocarditis following vaccination with Moderna compared with Pfizer (low certainty). Among 12-17-year-old females, we are uncertain about the incidence of myocarditis following vaccination with Moderna compared with Pfizer (very low certainty), due to inconsistency from a single study reporting findings that are contradictory to the evidence across all other age/sex categories.
- We identified 1 new study reporting on 18-29-year-old males and females and 2 new studies reporting on 18-39year-old males and females. We continue to conclude that among 18-29-year-old males and females and 18-39year-old females, the incidence of myocarditis is probably at least 2-3 times higher after vaccination with Moderna compared to Pfizer (moderate certainty). Among 18-39-year-old males we now conclude that the incidence of myocarditis is probably 2-5 times higher after vaccination with Moderna compared to Pfizer (moderate certainty).
- We identified 2 new studies reporting on 30-39-year-old males and females, providing increased certainty for . these groups. In 30-39-year-old males we are now certain that there is a higher incidence of myocarditis after vaccination with Moderna compared to Pfizer (high certainty). Among 30-39-year-old females, we now conclude that the incidence of myocarditis may be higher after vaccination with Moderna compared to Pfizer (low certainty).
- We identified 1 new study reporting on  $\geq$ 40-year-old males and females. In  $\geq$ 40-year-old males we are now uncertain about the incidence of myocarditis after Moderna compared to Pfizer. We continue to conclude that there may be a higher incidence of myocarditis after vaccination with Moderna compared to Pfizer in ≥40-year-old females (low certainty).

#### Moderna versus Pfizer, after dose 3 (monovalent)

- We identified 1 new study reporting on Moderna vs Pfizer after a monovalent dose 3. •
- Among 18-29-year-old males, there may be a higher incidence of myocarditis after vaccination with a third monovalent dose of Moderna compared with Pfizer (low certainty).
- Among 18-29-year-old females, there may be no difference in the incidence of myocarditis after vaccination with a • third monovalent dose of Moderna compared to Pfizer (low certainty).
- Among 30-39-year-old males, there may be a lower incidence of myocarditis after vaccination with a third monovalent dose of Moderna compared to Pfizer (low certainty).
- Among 30-39-year-old females there may be a higher incidence of myocarditis after vaccination with a third monovalent dose of Moderna compared to Pfizer (low certainty).
- Among ≥40-year-old males, we continue to conclude that the incidence of myocarditis may be higher after vaccination with a third monovalent dose of Moderna compared with Pfizer (low certainty). Among ≥40-year-old females we remain uncertain about any difference in incidence after vaccination with a third monovalent dose of Moderna compared to Pfizer (very low certainty).

## Moderna versus Pfizer, bivalent booster doses

- We identified 2 new studies reporting on Moderna vs Pfizer after a bivalent booster dose. •
- In both 5-11-year-olds (both sexes) and ≥12-year-olds (both sexes), there may be no difference in the incidence of myocarditis after a bivalent booster dose of Moderna compared to Pfizer (low certainty).

### Homologous vs heterologous vaccine for dose 2

- We did not identify any new studies reporting on homologous vs heterologous dosing regimens.
- Among 16-24-year-old males and females, 25-39-year-old males, and ≥40-year-old males and females, the incidence of myocarditis may be higher after mRNA vaccination with a heterologous dose 2 compared to homologous dose 2 (low certainty).
- For females 25-39 years-old, we are uncertain about any difference in the incidence of myocarditis after mRNA . vaccination with a heterologous dose 2 compared to homologous dose 2 (very low certainty).

# Clinical comorbidities: With vs without a positive COVID-19 test before vaccination, dose 1 or 2

We did not identify any new studies comparing individuals with vs without a positive COVID-19 test before • vaccination. Among individuals with a history of COVID-19 infection, we are uncertain whether the incidence of myocarditis differs after vaccination with dose 1 or dose 2 of an mRNA vaccine compared to those without a history of COVID-19 infection (very low certainty for each dose).

## Dose interval: Dose 1 to Dose 2

- We did not identify any new studies reporting on dose interval between dose 1 and dose 2. .
- In both 12-29-year-olds and ≥30-year-olds (both sexes combined), the incidence of myocarditis after dose 2 of an mRNA vaccine may be lower when administered  $\geq$ 27 days compared with <27 days after dose 1 (low certainty).

## Dose interval: Dose 2 to Dose 3

- We did not identify any new studies reporting on dose interval between dose 2 and dose 3.
- In 12-29-year-olds (both sexes combined) receiving dose 3 of Pfizer and ≥30-year-olds receiving dose 3 of Moderna, the incidence of myocarditis after dose 3 of may be lower when administered ≥170 days after dose 2 compared with <170 days after dose 2 (low certainty).
- In ≥30-year-olds receiving dose 3 of Pfizer, we are uncertain about whether incidence of myocarditis after dose 3 may be different across different dose timings due to evidence from a single study that contradicts the findings in dose timing across other age groups, doses, and mRNA products (very low certainty).

# Mvocarditis and/or pericarditis

# **Clinical Comorbidities**

- We identified no new studies reporting on clinical comorbidities and myocarditis and/or pericarditis.
- Studies reporting on these associations only reported across both sexes and all ages; therefore, the applicability to myocarditis in certain individuals such as males 12-29 years of age (where few individuals may have the condition e.g. hypertension or cardiovascular disease) is uncertain.
- There may be a higher incidence of myocarditis or pericarditis after vaccination with an MRNA vaccine (low • certainty) in individuals with the following: taking anti-inflammatory medications, cancer, cardiovascular conditions, hematologic conditions, previous infection (other than COVID-19), and rheumatic conditions.
- We are uncertain about whether there is an association with higher incidence for individuals with . immunocompromised or pulmonary conditions.

## Race

We identified no new studies reporting on myocarditis and/or pericarditis by race. There may be no difference in incidence of myocarditis or pericarditis after vaccination with an mRNA vaccine in black individuals compared with white (low certainty).

#### Pericarditis

## Moderna versus Pfizer, after dose 2

We identified no new studies reporting on pericarditis after Moderna compared with Pfizer in 18-29-year-old males and continue to conclude there is probably a higher incidence of pericarditis after vaccination with Moderna compared with Pfizer (moderate certainty).

- We identified no new studies reporting on 18-39-year-old males, and our conclusions for this groups have not changed. We continue to have moderate certainty that among 18-39-year-old males and females and ≥40-yearold males and females, there is probably a higher incidence of pericarditis after vaccination with Moderna compared with Pfizer (moderate certainty).
- We identified no new studies reporting on 30-39-year-old males and females continue to conclude there is
  probably a higher incidence of pericarditis after vaccination with Moderna compared with Pfizer (moderate
  certainty).

#### Moderna versus Pfizer, after bivalent booster doses

- We identified 1 new study reporting on Moderna vs Pfizer after a bivalent booster dose.
- In ≥12-year-olds (both sexes), there may be no difference in the incidence of pericarditis after a bivalent booster dose of Moderna compared to Pfizer (low certainty).

#### Homologous vs heterologous vaccine for dose 2

We identified no new studies reporting on pericarditis by homologous vs. heterologous vaccine dosing. For 16-24, 25-39, and ≥40y year old males and females we are uncertain whether the incidence of pericarditis differs after vaccination with a heterologous dose 2 of Moderna compared with homologous Moderna or Pfizer (very low certainty).

#### KQ3: Short-term Clinical Course

#### Children younger than 12 years

- Similar to the previous update, we found no additional case series reporting on the short-term clinical course of
  myocarditis after mRNA vaccination in children younger than 12 years old. The lack of new case series in this age
  group is perhaps not surprising, given the very low incidence of myocarditis after mRNA vaccination identified in
  KQ1 for this age group.
- One case series reported on the short-term (<4 weeks) clinical course of myocarditis after mRNA vaccination in children younger than 12 years old (mean 9 years, range 9 to 11). Among the 8 confirmed cases of myocarditis, 50% were males. All received the Pfizer vaccine product (Moderna is not authorized for younger than 18 years old).</li>
- 75% of cases presented with symptoms after the second dose, at about 3 days (range 0 to 12) after any dose. Among tested individuals, 50% had abnormal EKG and 20% had abnormal echocardiogram. Among six patients for which outcomes were known, the symptoms resolved in five and one was still recovering.

#### After third dose

- We found no additional case series reporting on the short-term clinical course of myocarditis after a third (or subsequent) dose of an mRNA vaccine.
- Among the 32 cases previously identified, all received the Pfizer vaccine and had been hospitalized. All were discharged at follow-up.

#### KQ4: Longer-term Outcomes

- In addition to nine reports from the previous synthesis,<sup>24 38 53-59</sup> three new reports were included for longer-term (≥12 weeks) outcomes.<sup>11-13</sup> Overall, findings were similar to the previous update.
- Across 10 studies with unique patients, 278 cases were followed up at least 12 weeks (medians ranged from 13 to 27 weeks). Two reports with at least 12-week follow-up of at least 519 cases reported to Vaccine Adverse Events Reporting System (VAERS) in the US may include cases that overlap with the other reports from the five distinct samples in the other US-based reports.<sup>12 24</sup> Eight (67%) studies had follow-up data for ≥90% of patients with myocarditis;<sup>11 13 53-55 57-59</sup> four studies had lower rates of follow-up (30-76%).<sup>12 24 38 56</sup> Follow-up for completion of health-related quality of life questionnaires was suboptimal (71%) in one study of patients with myocarditis reported to VAERS.<sup>12 68</sup> One death was reported in one study.<sup>13</sup>
- Eight reports presented follow-up MRI findings for 228/651 (35%) patients followed up) with a range of median follow-up from 13 to 27 weeks.<sup>12 38 53-57 59</sup> Improvements were seen in late gadolinium enhancement, positive findings persisted in many patients (139/228, 61%) indicating some residual fibrosis. At follow-up, LVEF% was >50% for all patients in which it was reported (41/41, 100%).<sup>53 55 57 59</sup>

- Ongoing chest pain during follow up (range in medians: 13 to 27 weeks) was reported by 139/481 (29%) patients reporting this outcome.<sup>11 12 38 53 56 57 59</sup> Other symptoms commonly reported by patients included fatigue (91/455, 20%), shortness of breath (85/455, 19%), and palpitations (80/455, 18%).
- At follow-up,<sup>12 38 53</sup> 110/437 patients (25%) were still taking medications related to myocarditis after 13 to 27 weeks or at last healthcare provider encounter.
- 72% of unique patients (72/99) were recovered with no symptoms after 13 to 24 weeks median follow-up. Among 393 patients 12 to 29 years old identified from the VAERS database for whom healthcare providers reported follow-up outcomes after a median of 191 days (~27 weeks),<sup>12</sup> 81% were considered fully recovered by their provider based on their clinical assessment and testing information. Cardiac MRI abnormalities were detected in 81/151 (54%) of those re-tested.
- Among 357 VAERS cases completing self-report follow-up guestionnaires (median 191 days),<sup>12</sup> 6 patients (2%) reported readmission to hospital. EuroQol 5D-5L, which measures health-related quality of life, was completed by 249/357 (71%) patients who reported problems with anxiety/depression (114/249, 46%), 30% (n=74) pain (74/249, 30%), and ongoing problems participating in their usual activities (49/249, 21%). Few (15/267, 6%) of affected individuals missed school or work in the 2 weeks before follow-up due to myocarditis

#### CQ1: Hypothesized Mechanisms

The previous version of this report has details of papers describing many hypothesized mechanisms for SARS-CoV-2 vaccine-associated myocarditis. For this version, only studies reporting empirical data on 5 or more patients with suspected myocarditis after SARS-CoV-2 vaccination were included; one study carried forward from the earlier versions<sup>60</sup> and six new studies were found.<sup>14-19</sup> A narrative summarizing each study is presented below, and Table 5 includes details and findings of the included studies. We have not used green font for this section which is all new.

## Studies involving biopsy (n=4)

- Two studies examined patients with and without suspected myocarditis after vaccination. One study from . Germany evaluated neutralizing autoantibodies targeting the endogenous interleukin-1 receptor antagonist (IL-1RA), which inhibits interleukin-1 signaling and inflammation, and progranulin, which inhibits tumor necrosis factor signaling.<sup>16</sup> Among 61 patients (80% male; 17-79 years of age) with suspected myocarditis having biopsy (timing not reported), 40 had confirmed myocarditis (criteria not reported), among which anti-IL-1RA antibodies were found in 9 of 12 patients (75%) younger than 21 years of age, compared with 3 of 28 patients (11%) 21 years of age or older. Anti-IL-1RA antibodies were not detectable in the 21 patients in whom biopsy ruled out the diagnosis of myocarditis, and were observed in only 2 of 214 vaccinated control participants (1%) and in 2 of 125 participants (2%) who had histologically proven myocarditis that had been diagnosed before the Covid-19 pandemic. IL-1RA plasma levels correlated with markers of cardiac damage (troponin T, creatine kinase, creatine kinase MB, or pro-B-type natriuretic peptide), cardiac-tissue infiltration of CD3+ T cells and CD68+ macrophages, and systemic inflammation (C-reactive protein). These antibodies impaired IL-1RA bioactivity in vitro, were associated with low circulating levels of IL-1RA. A hyperphosphorylated IL-1RA isoform was observed in young male patients with biopsy-confirmed myocarditis after vaccination. The authors suggest that the evidence points toward a transient hyperphosphorylation of IL-1RA preceding a breakdown of peripheral immune tolerance.
- Another study from Germany performed autopsy in 5 deceased patients (mean age 58 years) with confirmed (Dallas criteria) myocarditis, 4-10 days after vaccination mainly (4 of 5) after their first dose.<sup>15</sup> All cases showed a consistent phenotype with: i) focal interstitial lymphocytic myocardial infiltration, in three cases accompanied by demonstrable microfocal myocyte destruction, ii) T-cell dominant infiltrate with CD4 positive T-cells outnumbering CD8 positive T-cells by far, and iii) frequently associated with T-cell infiltration of epicardium and subepicardial fat tissue revealing a similar immune phenotype (CD4 > > CD8). Similar (epi-)myocardial T-cell infiltration was not found among either 20 autopsies performed on bodies found dead within 20 days following an anti-SARS-CoV-2 vaccination or age- and sex matched cohorts from three independent periods from the authors' autopsy-files. Autopsy findings suggested death due to an arrhythmic cause. An inflammatory foci, predominantly in the right heart, which may suggest a gradual blood-stream derived dilution effect, allowed some speculation that inadvertent intravascular vaccine injection may have contributed.
- A US study conducted histopathology and gene expression (rapid turnaround reverse-transcription guantitative polymerase chain reaction) in patients with myocardial injury (6 with suspected post-vaccination myocarditis, 7 with post-COVID-19 myocardial injury and 95 age and sex-matched biobanked control heart samples) for mRNA expression of 7 candidate genes including ACE2, ACE, and other genes whose protein products could be

Canadian Institutes Instituts de recherche of Health Research en santé du Canada

involved in myocardial dysfunction, inflammation, and coagulopathy.<sup>14</sup> None of the 5 patients with suspected postvaccination myocarditis having biopsy had myocardial inflammatory infiltrate; proinflammatory biomarkers were normal and 3 cases demonstrated no evidence of an inflammatory infiltrate or microthrombi, and only nonspecific abnormalities with no evidence of loss of contractile elements. Further, only 1 of 7 patients with injury post-COVID-19 had definitive myocarditis. These findings may have been from recovery from inflammation or biopsy sampling error. Myocardial gene expression (i.e., down-regulation in ACE2, ACE2/ACE ratio, AGTR1 [encoding type 1 receptor and a biosensor of angiotensin II generation], and ITGA5 [possible CoV-2 co-receptor whose encoded protein binds to and is co-regulated with ACE2 in eccentric remodeling] and upregulation in ACE and F3 [tissue factor]) was altered to predispose to inflammation, thrombosis, and contractile dysfunction. Changes noted up to 137 or 182 days post-infection diagnosis, reflecting ongoing injury process, or sustained S protein levels. The authors propose that COVID-19 and post-mRNA vaccine myocardial injury may have a common molecular pathology, and that if translated into protein changes, the adjustments in ACE2 and ACE mRNA expression would have negative implications for cardiac myocyte and endothelial cell function as well as for promoting a procoagulant state and predisposing to inflammation. Upregulation of F3 gene may promote thrombosis and inflammation.

Lacking any control group, another study from Germany performed immunohistochemical analyses from biopsies (timing not reported) in 15 patients (60% male, mean age 38 years) with suspected myocarditis after COVID-19 vaccination (11 after Pfizer [9 after second dose], 4 after non-mRNA) and reduced ejection fraction (mean LVEF 30%).60 Analyses revealed myocardial inflammation in 14 of 15 patients, with active myocarditis according the Dallas criteria (n = 2), severe giant cell myocarditis (n = 2) and inflammatory cardiomyopathy (DCMi; n = 10). When used, cMRI was able to detect myocardial inflammation in only 33.3% (2/6) of the cases. The SARS-CoV-2 spike protein was found in sparse cells (cardiomyocytes) in 9 of 15 cases. Except the cases with active myocarditis, giant cell myocarditis, and one case of DCMi, CD4+-T-cell-to-CD8+-T-cell ratio was ≥1, suggesting a predominantly autoimmunological origin of the observed inflammation. The expression of SARS-CoV-2 spike protein within the heart and the dominance of CD4+ lymphocytic infiltrates (considered a major driver of autoimmune myocarditis) indicate an autoimmunological response to the vaccination. Expression of HLA-DR (associated strongly several autoimmune diseases) was increased in 11 of 14 (79%) patients, supporting an autoimmunological contribution to myocardial inflammation after vaccination. No patient had increased perforin+ cells, indicating no contribution of cytotoxic events following the COVID-19 vaccination.

#### Studies involving immunoprofiling (n=3)

- Three studies performed various immunological tests in patients with and without suspected myocarditis after vaccination. Among 16 hospitalized patients with myocarditis (81% male, 88% after 2nd or 3rd dose, mean age 16 years [range 12-21]) and 45 healthy age-matched mRNA vaccinated controls, authors of a US study performed extensive antibody profiling, including tests for SARS-CoV-2-specific humoral responses and assessment for autoantibodies or antibodies against the human-relevant virome, SARS-CoV-2-specific T-cell analysis, and cytokine and SARS-CoV-2 antigen profiling (mean 4 [exposed] and 14 days [controls] after vaccination).<sup>18</sup> Most responses for antibody profiling (i.e. humoral responses of anti-spike or anti-receptor binding protein, IgM, IgG, or IgA levels, self-antibodies) and T-cell analysis were essentially indistinguishable between the individuals who did and did not develop postvaccine myocarditis; there was a modest increase in cytokine production (i.e., interleukin (IL)-8, IL-6, tumor necrosis factor- $\alpha$ , IL-10, interferon- $\gamma$ , and IL-1 $\beta$ ) suggesting likely innate inflammatory activation. Total leukocytes, specifically neutrophils, were significantly increased in individuals with postvaccine myocarditis. There were markedly elevated levels of full-length spike protein (33.9±22.4 pg/mL), unbound by antibodies, in the plasma of individuals with postvaccine myocarditis, whereas no free spike was detected in asymptomatic vaccinated control subjects. No significant differences were found in antibody neutralization capacities. These results suggest that postvaccine myocarditis is associated with normal adaptive and T-cell immunity but modest innate activation. Elevated levels of free spike protein in circulation, unbound by anti-spike antibodies, appear to correlate with cardiac troponin T levels and innate immune activation with cytokine release. The spike antigen itself, which appears to evade antibody recognition rather than invoking immune hyperactivation, may contribute to myocarditis in these individuals.
- A study in Hungary performed routine laboratory testing and testing of humoral and cellular immune response to COVID-19 vaccination in 12 males (22 ± 7 years old, 81% after second dose) with suspected post-vaccine myocarditis and 23 age- and sex-matched controls with similar vaccine exposure.<sup>17</sup> 25% versus 91% had previous COVID-19 infection but anti-NCP (IgG, IgM) testing showed no difference between the two groups. Findings indicated no difference in the humoral immune response (i.e., anti-SARS-CoV-2 modified nucleocapsid protein (NCP)-IgG, anti-SARS-CoV-2 NCP-IgM, SARS-CoV-2 spike (S) protein receptor-binding domain (RBD) Ig,

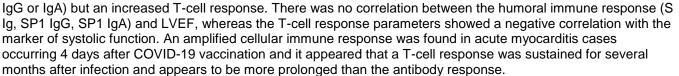

Canadian Institutes Instituts de recherche of Health Research en santé du Canada

Public Health

Agence de la santé Agency of Canada publique du Canada

A US study enrolled 23 patients with post-vaccine myocarditis (13 at 2-5 days after vaccination [100% males, mean age 14.6 years] and 10 during 2-5 weeks after resolution of myocarditis) and 10 healthy controls 2-4 weeks after their second dose of mRNA vaccine, both groups with no history of COVID-19, to examine serum samples for gualified SARS-CoV-2 pseudovirion neutralization assay using SARS-CoV-2 WA-1 strain, the five variants of concern (Alpha, Gamma, Beta, Delta, and Omicron) and two variants of interest (Lambda and Mu, and seroreactivity to SARS-CoV-2 recombinant spike- receptor binding domain from WA-1 and Omicron.<sup>19</sup> Among those with myocarditis, there was an increase in neutralizing values of 2 to 8-fold from the acute to post-acute time-point across all SARS-CoV-2 variants; neutralization of Omicron was reduced by 31.8-fold compared with the vaccine homologous WA1/2020 and the end-point titer of serum IgG binding to WA1/2020-RBD was 13.7-fold higher than to Omicron. In the healthy controls, neutralizing antibody response was reduced against SARS-CoV-2 variants ranging from 1.2-fold for Alpha to 3.3-fold against Beta compared with vaccine-homologous WA1/2020 and neutralization titers against Omicron were reduced by 27.2-fold with 50% having no measurable neutralization titers compared with vaccine-homologous WA1/2020. In summary, post-vaccination neutralization titers were significantly higher for children with vaccination-induced myocarditis (2-5 weeks post-vaccination) compared with healthy control children (2-4 weeks post-vaccination) against vaccine-homologous WA1/2020 as well as trended higher for Omicron (not statistically significant), possibly suggesting higher immunogenicity of mRNA vaccines in the vaccine-induced myocarditis children. Children with vaccination-induced myocarditis made a robust antibody response that trended higher than healthy children.

#### **Future Directions**

- As regular COVID-19 boosters become a reality, continued surveillance of myocarditis after mRNA vaccines is needed to support continued decision making, especially for monovalent booster doses and bivalent vaccines.
- Additional monitoring of populations with clinical comorbidities of interest (e.g., previous history of myocarditis, immunocompromised, etc.) is also needed in order to protect the already medically vulnerable. Data reported by age group and sex is necessary to understand whether risk may differ across groups and to determine the absolute risk difference.
- Studies with more than 6 months' follow-up for vaccine-related myocarditis are needed to better understand the natural history and long-term impacts of these events.
- The available studies on biological mechanisms are diverse in their methods and populations, such that additional work is required to better enable comparisons across studies and thus further support any proposed mechanisms.

### **Tables**

## Table 1: Summary of Findings for Incident Rates after Receipt of Either mRNA Vaccine (KQ1)

Sex	Age	Studies (data source and date) Country *passive surveillance	Risk interval; Confirmed cases (Y/N)	Incidence per million doses of either mRNA vaccine unless otherwise stated *weighted average across age groups ‡weighted average across products †excess incidence	Conclusions	Certainty about conclusions using GRADE

Green text = new evidence identified by Feb 2023 update. Blue text = increased certainty since last report; red text = decreased certainty since last report. BNPV - Base Nationale de Pharmacovigilance is the French national spontaneous reporting database.

DVR/DPR - Danish Vaccination Register & Danish Patient Register

eHRSS - The Electronic Health Record Sharing System (eHRSS) is a territory-wide, patient-oriented electronic sharing platform which enables authorised healthcare providing organisations in the public and private sectors to access and share participating patients' electronic health records (eHR) for healthcare purposes.

#### HSA - Health Science Authority of Singapore

IDF – Israeli Defense Forces

**NHS** - National Health Service, which is the single-payer national health system in the UK.

NIMS - NHS Immunisation Management Service database

**PCORnet** - the National Patient-Čentered Clinical Research Network, a national network of networks that facilitates access to health care data and interoperability through use of a common data model across participating health care systems (https://pcornet.org/data). The PCORnet Common Data Model contains information captured from EHRs and other health care data sources (e.g., health insurance claims), including demographic characteristics, diagnoses, prescriptions, procedures, and laboratory test results, among other elements.

**SAEFVIC** - Surveillance of Adverse Events Following Vaccination in the Community (SAEFVIC) is the state-wide vaccine safety service for the Australian state of Victoria. SAEFVIC comprises central reporting enhanced passive and active surveillance systems integrated with clinical services and has been operating since 2007. **SNDS** - French National Health Data System (Système National des Données de Santé)

**TGA** - The Therapeutic Goods Administration is the medicine and therapeutic regulatory agency of the Australian Government. As part of the Department of Health, the TGA regulates the quality, supply and advertising of medicines, pathology devices, medical devices, blood products and most other therapeutics.

VAERS – Vaccine Adverse Events Reporting System is a passive surveillance system in the United States to which healthcare providers and patients can report adverse events from medical products, including vaccines. Providers are required to report to VAERS adverse events that occur after receipt of any COVID-19 vaccine. The VAERS system was not designed to assess causality; therefore, VAERS data generally cannot be used to determine whether a causal association between an adverse event and a vaccine exists

**VSD** - Vaccine Safety Datalink is a collaborative project between CDC's Immunization Safety Office and nine health care organizations to monitor safety of vaccines and conduct studies about rare and serious adverse events following immunization. VSD uses electronic health data from each participating site including the kind of vaccine given to each patient, date of vaccination, and other vaccinations given on the same day, and information on medical illnesses that have been diagnosed at doctors' offices, urgent care visits, emergency department visits, and hospital stays.

#### Notes:

<sup>1</sup>Crude incident rates were converted to excess incidence rates using the estimated adjusted IRRs from the study (excess=crude incidence –(crude incidence / aIRR); for males: aIRR 16-19 y 8.96 (95% CI, 4.50 to 17.83); 20-24 y 6.13 (95% CI 3.16 to 11.88); 25-29 y 3.58 (95% CI 1.82 to 7.01);  $\geq$ 30 y 1.00 (95% CI, 0.61 to 1.64) (note: for the 30-39y old data we used an average of the 25-29 and  $\geq$ 30y aIRRs); for females: 16-19y 2.95 (0.42–20.91), 20-24 y 7.56 (1.47–38.96), 25-29y 0,  $\geq$ 30y 0.82 (0.33–2.02)(not used)

#### **Explanations for GRADE:**

In the plain-language conclusions, we have used "probably", "may be" and "uncertain" to reflect level of certainty in the evidence based on GRADE of moderate, low, or very low, respectively. GRADE certainty in blue text indicates increased certainty over the previous synthesis; red text indicates decreased certainty compared with the previous synthesis.

<sup>a</sup> Rated up for evidence that is highly consistent and finding very low (i.e., zero or near-zero) incidence across multiple studies.

<sup>b</sup> Rated up for estimated incidence likely to be more than twice our clinically important threshold of 20 cases per million, highly unlikely to be seen by chance and credible to be higher than for other age categories. (Citation: Guyatt et al. 2011 <u>https://doi.org/10.1016/j.jclinepi.2011.06.004</u>)

<sup>c</sup> Rated down for inconsistency for only one study or for a large incidence range within one age/sex category

<sup>d</sup> Rated down for indirectness of findings to entire population, based on large differences in estimates in analyses for males across age groups indicating one estimate (or even a range of estimates) for all ages (for both sexes or males) is not credible.

e Rated down for risk of bias from reliance of estimate on passive surveillance/spontaneous reporting.

The Covid Research Co

Green text = new evidence identified by Feb 2023 update. Blue text = increased certainty since last report; red text = decreased certainty since last report. BNPV - Base Nationale de Pharmacovigilance is the French national spontaneous reporting database for drug products including vaccines.

**COVaxON** - Covid-19 Vaccinations Ontario is a central data repository for COVID-19 vaccine data and reporting in Ontario, administered by the Ontario Ministry of Health. **EULAR COVAX**- The European Alliance of Associations for Rheumatology Coronavirus Vaccine is a physician-reported registry; data are entered voluntarily by rheumatologists or other members of the clinical rheumatology team; patients are eligible for inclusion if they registry have a pre-existing inflammatory/rheumatic and musculoskeletal disease or non-inflammatory rheumatic and musculoskeletal disease (NI-RMD) and have received one or more doses of any vaccine against SARS-CoV-2. **ISS/AIFA** - An active surveillance database based on Regional health care claims was set up by the Italian National Institute of Health (ISS) and the Italian Medicines Agency (AIFA) to provide real-world data on SARS-CoV-2 vaccine safety.

**NIMS** - The English National Immunisation (NIMS) Database of COVID-19 vaccination includes data on vaccine type, date and doses for all people vaccinated in England. **SAEFVIC** - Surveillance of Adverse Events Following Vaccination in the Community (SAEFVIC) is the state-wide vaccine safety service for the Australian state of Victoria. SAEFVIC comprises central reporting enhanced passive and active surveillance systems integrated with clinical services.

**SNDS** - the French administrative health care database covers around 99% of the French population and includes anonymized data on socio-demographics, medical characteristics, ambulatory care, hospitalizations, diagnosis, drugs and procedures, mortality, and costs.

VHA - Veteran's Health Administration is a nationalized healthcare service in the United States that provides healthcare and healthcare-adjacent services to Veterans through the administration and operation of healthcare facilities including inpatient, outpatient, and care home facilities.

VAERS – Vaccine Adverse Events Reporting System is a passive surveillance system in the United States to which healthcare providers and patients can report adverse events from medical products, including vaccines. Providers are required to report to VAERS adverse events that occur after receipt of any COVID-19 vaccine. The VAERS system was not designed to assess causality; therefore, VAERS data generally cannot be used to determine whether a causal association between an adverse event and a vaccine exists

**VSD** - Vaccine Safety Datalink is a collaborative project between CDC's Immunization Safety Office and nine health care organizations to monitor safety of vaccines and conduct studies about rare and serious adverse events following immunization. VSD uses electronic health data from each participating site including the kind of vaccine given to each patient, date of vaccination, and other vaccinations given on the same day, and information on medical illnesses that have been diagnosed at doctors' offices, urgent care visits, emergency department visits, and hospital stays.

Notes:

<sup>1</sup>this study reported IRRs calculated using a self-controlled case series design. In this study design, individuals serve as their own controls and risk estimates in pre- and post-intervention intervals are calculated within individuals.

<sup>2</sup>Because of the large overlap in data between males 18-29y and 18-39y, we only downrated 18-29y once for inconsistency despite the large differences in effects reported between studies.

<sup>3</sup>Weighted averages across age groups were calculated based on contribution of each age to the review-level age category.

<sup>4</sup> We did not rate down for indirectness because the incidence of pericarditis differs less across age groups than myocarditis.

**Explanations for GRADE** 

In the plain-language conclusions, we have used "probably", "may be" and "uncertain" to reflect level of certainty in the evidence based on GRADE of moderate, low, or very low, respectively. GRADE certainty in blue text indicates increased certainty over the previous synthesis; red text indicates decreased certainty compared with the previous synthesis. Upper-case superscripts indicate rating down twice for that domain.

<sup>a</sup> Rated down for inconsistency or due to only one study providing estimates

<sup>b</sup> Rated down for risk of bias from reliance on passive surveillance/spontaneous reporting

<sup>c</sup> Rated down for imprecision for large range over conclusion threshold, small sample size (<10,000 per group), and/or very low event rate.

<sup>d</sup> Rated down for indirectness to whole population, based on large differences in estimates in analyses for males across age groups indicating one estimate (or even a range of estimates) for all ages (for both sexes or males) is not credible.

### Table 5. Studies on mechanisms of myocarditis after vaccination (CQ1)

Author; Citation; Country	Methods	Sample(s): E: exposed to myocarditis after vaccination NEV: no myocarditis after vaccine	Findings	Authors' Conclusions
Thurner et al. IL-1RA antibodies in myocarditis after SARS- CoV-2 vaccination. <i>N</i> <i>Engl J Med</i> 387;16. doi: 10.1056/NEJMc2205667 Germany	Evaluated neutralizing autoantibodies targeting the endogenous interleukin-1 receptor antagonist (IL-1RA), which inhibits interleukin-1 signaling and inflammation, and progranulin, which inhibits tumor necrosis factor signaling. Endomyocardial biopsy to confirm myocarditis.	NE: other, as described E: 69 (80% male; 14 to 79 years of age) who had clinically suspected myocarditis; 40 of 61 with endomyocardial biopsy had histologically confirmed myocarditis (criteria not reported) NEV: 214 healthy adults who had samples obtained 1 week after receipt of the second dose of SARS-CoV- 2 vaccine NE: 127 patients with myocarditis whose samples were obtained before 2020	E: in 40 with confirmed myocarditis: anti–IL-1RA antibodies were found in 9 of 12 patients (75%) younger than 21 years of age, as compared with 3 of 28 patients (11%) 21 years of age or older. Anti–IL-1RA antibodies were not detectable in the 21 patients in whom biopsy ruled out the diagnosis of myocarditis. IL-1RA antibody– positive patients with biopsy-confirmed myocarditis had an early onset of symptoms, which occurred mostly after receipt of the second vaccine dose, and a milder course of myocarditis than patients with biopsy-confirmed myocarditis but without anti–IL-1RA autoantibodies. NEV and NE: IL-1RA antibodies were observed in 2 of 214 vaccinated control participants (1%) and in 2 of 125 participants (2%) who had histologically proven myocarditis that had been diagnosed before the Covid-19 pandemic.	<ul> <li>Neutralizing antibodies against IL-1RA and a hyperphosphorylated IL-1RA isoform were observed in young male patients with biopsy-confirmed myocarditis after the receipt of SARS-CoV-2 mRNA vaccine. These antibodies impaired IL-1RA bioactivity in vitro, were associated with low circulating levels of IL-1RA, and were found in patients with biomarker evidence of cardiac damage and inflammation.</li> <li>Previous data that had been obtained from patients with critical Covid-19 did not support the cross-reactivity of purified IL-1RA antibodies with structural proteins of SARS-CoV-2, including the spike protein, which argues against virus- or vaccine driven molecular mimicry.</li> <li>Current evidence points toward a transient hyperphosphorylation of IL-1RA preceding a breakdown of peripheral immune tolerance.</li> <li>In Western blots of total plasma protein, antibodies to IL-1RA, but prominent immune (IgM or IgG)-complexed protein with an atypical IL-1RA isoform occurred exclusively in patients who were seropositive for anti-IL-1RA antibodies. This additional IL-1RA isoform was hyperphosphorylated at threonine position 111, which had been observed previously in adult patients with critical Covid-19 and in patients with MIS-C. In contrast to our observations in patients with myocarditis after SARS-CoV-2 vaccination, IL-1RA was not hyperphosphorylated in any of the samples that had been obtained from control participants.</li> <li>IL-1RA plasma levels correlated with markers of cardiac damage (troponin T, creatine kinase, creatine kinase MB, or pro-B-type natriuretic peptide), cardiac-tissue infiltration of CD3+ T cells and CD68+ macrophages, and systemic inflammation (C-reactive protein).</li> </ul>

Schwab et al. Autopsy-based histopathological characterization of myocarditis after anti-SARS -CoV-2-vaccination. <i>Clinical Research in</i> <i>Cardiology</i> https://doi.org/10.1007/s 00392-022-02129-5 Germany	Autopsy-based histopathological characterization, including immunohistochemistry	E: 5 patients (40% male; mean age 58 years [46-75]; 80% after first dose; 0% with previous COVID-19) with post vaccine myocarditis via Dallas criteria, assessed 4- 10 days after vaccination NEV: 20 persons who had died unexpectedly and within 20 days after anti- SARS-CoV-2 vaccination but not having myocarditis NE: Three age- and sex matched cohorts from autopsy files (covering the years 2005/2006, 2010/2011 and 2015/2016) were retrieved and the myocardial samples were evaluated for the presence and phenotype of inflammatory infiltrates.	<ul> <li>Histology showed patchy interstitial myocardial T-lymphocytic infiltration, predominantly of the CD4 positive subset, associated with mild myocyte damage.</li> <li>CD3-positive T-cells by far outnumbered the few CD20-positive B-cells detected, and most T-cells belonged to the CD4-positive subset. T cells were negative for Tbet as a marker for Th1 cells, GATA3 as a marker for Th2 cells, D2-40, as a marker for Th17 cells.</li> <li>Microfocal myocyte injury was demonstrable in three cases.</li> <li>In 4 cases, an inflammatory infiltration of the epicardium and the subepicardial fat tissue was concomitantly found and revealed an identical immunophenotype. (T-cell dominant; CD4 &gt;&gt; CD8).</li> <li>Autopsy findings suggested death due to acute arrhythmogenic cardiac failure. All cases lacked significant coronary heart disease, acute or chronic manifestations of ischaemic heart disease, manifestations of cardiomyopathy or other signs of a pre-existing, clinically relevant heart disease.</li> <li>One case had detection of human herpes virus 6 (HHV6) which may have caused the myocarditis.</li> </ul>	All cases showed a consistent phenotype: (A) focal interstitial lymphocytic myocardial infiltration, in three cases accompanied by demonstrable microfocal myocyte destruction. (B) T-cell dominant infiltrate with CD4 positive T-cells outnumbering CD8 positive T-cells by far; (C) frequently associated with T-cell infiltration of epicardium and subepicardial fat tissue revealing a similar immune phenotype (CD4 > > CD8). A comparable (epi-)myocardial (T-cell) infiltration was neither found in any of the other 20 autopsies performed on bodies found dead within 20 days following an anti-SARS-CoV-2 vaccination nor in the age- and sex matched cohorts from three independent periods from our autopsy-files. We recorded inflammatory foci predominantly in the right heart, which may suggest a gradual blood- stream derived dilution effect and based on this finding it is at least tempting to speculate that inadvertent intravascular vaccine injection may be contributive. Further studies and extended registry are needed to identify persons at risk for this potentially fatal AEFI and may be aided by detailed clinical, serological, and molecular analyses which were beyond the scope of this study.
Altman et al. Myocardial injury and altered gene	Endomyocardial biopsy, histopathology and gene expression (rapid turnaround	E: 6 patients (4 males; 36 ± 13 years; no previous cardiac history in 5); with myocardial injury after	E: 1 of 6 had myocarditis and no biopsy Biopsy – none had myocardial inflammatory infiltrate; proinflammatory biomarkers were normal and 3 cases demonstrated no evidence of an	COVID-19 and post–mRNA vaccine myocardial injury may have a common molecular pathology. Myocardial gene expression was altered to predispose to inflammation, thrombosis, and

expression associated with SARS-CoV-2 infection or mRNA vaccination. Am Coll Cardiol Basic Trans Science. 2022. https://doi.org/10.1016/j.j acbts.2022.08.005 US	reverse-transcription quantitative polymerase chain reaction for mRNA expression of 7 candidate genes including ACE2, ACE, and other genes whose protein products could be involved in myocardial dysfunction, inflammation, and coagulopathy)	mRNA vaccination, presenting with a clinical diagnosis of myocarditis (n=4 with gene expression 13, 32, 40, and 182 days after vaccination) NE1: 7 patients with myocardial injury ≤6 months after SARS-CoV-2 infection (n=6 with gene expression); all treated with remdesivir and dexamethasone, and anticoagulated and/or received antiplatelet agents, NE2: 95 control samples from both nonfailing (LVEF ≥0.50) and failing (LVEF ≥0.50) and failing (LVEF <0.35) LVs, using biobanked mid-distal interventricular septum samples from explanted organ donor or cardiac transplant recipient hearts (age -and sex- matched to NE1 group) and other controls from another biopsy study	<ul> <li>inflammatory infiltrate or microthrombi, and only nonspecific abnormalities with no evidence of loss of contractile elements</li> <li>Gene expression - mRNA abundance values that were similar to the COVID-19 data (NE1): none of the individual gene mRNA abundances had P values &lt;0.10 (range 0.12-0.44) between the NE1 and E groups and same directionality and statistically significant differences between E and controls as seen for NE1</li> <li>NE: Multiple protocol designated proinflammatory cytokines were within normal limits at the time of biopsy;</li> <li>Biopsy - 1 of 7 had definitive myocarditis and evidence of myocyte injury (myocytolysis and loss of contractile elements); 4 had other and 2 had no abnormalities</li> <li>Gene expression - compared with controls: - decreased ACE2 mRNA (-2.7 to -3.4-fold; P&lt;0.01), ACE2/ACE expression ratio (-6.1 to -9.0-fold; P&lt;0.01), AGTR1 (low-abundance mRNA that encodes the type 1 receptor and a biosensor of angiotensin II generation) (-2.7 to 4.4-fold; P&lt;0.05), ITGA5 mRNA (a possible CoV-2 co-receptor whose encoded protein binds to and is co-regulated with ACE2 in eccentric remodeling (-1.7 to 1.8-fold; P=0.01), full-length transcript (fITF) of the F3 or tissue factor (TF) gene</li> <li>increased ACE mRNA (2.1 to 2.8-fold; P&lt;0.05)</li> <li>no significant differences in angiotensinogen (AGT) mRNA</li> </ul>	contractile dysfunction. Changes were durable, noted up to 137- or 182-days post-infection diagnosis, reflecting ongoing injury process, or sustained S protein levels. Lack of biopsy & histology-confirmed myocarditis in E group possibly due to recovery from inflammation or EmBx sampling error. mRNA expression of candidate genes, selected for protein gene product likelihood of producing myocardial dysfunction, inflammation, or a prothrombotic state in response to Spike protein, exhibited similar changes, consisting of down- regulation in ACE2, ACE2/ACE ratio, AGTR1, and ITGA5 and upregulation in ACE and F3 (tissue factor). If translated into protein changes the adjustments in ACE2 and ACE mRNA expression would lead to much higher myocardial concentrations of angiotensin II, and lack of changes in AGT would indicate the myocardial renin-angiotensin system in COVID-19 patients was functionally imbalanced toward angiotensin II production, having negative implications for cardiac myocyte and endothelial cell function as well as for promoting a procoagulant state and predisposing to inflammation. Upregulation of F3 gene may promote thrombosis and inflammation. Targeted therapies could include intensive angiotensin II inhibitory and/or anticoagulation strategies including tissue factor inhibition.
Baumeier et al. Intramyocardial inflammation after COVID-19 vaccination: an endomyocardial biopsy-proven case	Endomyocardial biopsy with histopathology and immunohistochemical analysis	E: 15 patients (60% male, mean 38 years) with reduced ejection fraction (LVEF = 30 (14–39)%) and suspected myocarditis after COVID-19 vaccination (11	Immunohistochemical EMB analyses revealed myocardial inflammation in 14 of 15 patients, with active myocarditis according the Dallas criteria (n = 2), severe giant cell myocarditis (n = 2) and inflammatory cardiomyopathy (DCMi; n = 10). 11 of 15 had received Pfizer, 9 after dose 2.	The expression of SARS-CoV-2 spike protein within the heart and the dominance of CD4+ lymphocytic infiltrates (considered a major driver of autoimmune myocarditis) indicate an autoimmunological response to the vaccination.

## LIVING EVIDENCE SYNTHESIS: UPDATE #4 SUMMAI arche States arche

Country E: ex after NEV: vacci NE: c		Sample(s): E: exposed to myocarditis after vaccination NEV: no myocarditis after vaccine NE: other, as described	Findings	Authors' Conclusions		
series. <i>Int J Mol Sci.</i> 2022, 23, 6940. <u>https://doi.org/10.3390/ij</u> <u>ms23136940</u> Germany		after Pfizer, 4 after non- mRNA)	No viral pathogens detected. Diverse pattern of inflammatory markers, ranging from mild to severe degree of inflammation. When used, cMRI was able to detect myocardial inflammation in only 33.3% (2/6) of the cases From 14 patients with inflammation, 9 (64%) showed elevated infiltration of CD3+ T cells, 12 (86%) showed increased levels of CD45R0+ T- memory cells and LFA-1+ lymphocytes, 11 (79%) showed increased numbers of MAC-1+ macrophages and HLADR+- presenting cells, and none showed augmented levels of perforin+ cytotoxic cells. Cellular adhesion molecules ICAM-1 and VCAM-1 were normal in 12 patients. The SARS-CoV-2 spike protein was found in sparse cells (cardiomyocytes) in 9 of 15 cases. Except the cases with active myocarditis, giant cell myocarditis, and one case of DCMi, CD4+-T- cell-to-CD8+-T-cell ratio was ≥1, suggesting a predominantly autoimmunological origin of the observed inflammation.	Expression of HLA-DR was increased in 11 of 14 (79%) patients with evident inflammation. Due to the fact that HLA class II regions strongly associate with several autoimmune diseases, induction of HLA-DR in response to the vaccination supports an autoimmunological contribution to myocardial inflammation after vaccination. None of the patients showed increased presence of perforin+ cells, indicating no contribution of cytotoxic events following the COVID-19 vaccination.		
Yonker et al. Circulating spike protein detected in post– COVID-19 mRNA vaccine myocarditis. <i>Circulation.</i> 2023;147:00–00. DOI: 10.1161/CIRCULATION AHA.122.061025 US	Antibody profiling, including tests for SARS-CoV-2– specific humoral responses and assessment for autoantibodies or antibodies against the human-relevant virome, SARS-CoV-2– specific T-cell analysis, and cytokine and SARS-CoV-2 antigen profiling	E: 16 patients (81% male; 88% after 2 <sup>nd</sup> or 3 <sup>rd</sup> dose; mean 16 y [range 12-21]) who were hospitalized for myocarditis after mRNA SARS-CoV-2 vaccination (confirmed and probable via CDC criteria), sample collected mean 4 (1-19 d after vaccination) NEV: 45 healthy, asymptomatic, age-matched vaccinated control subjects, sample collected mean 14 (4-21) days after 2 <sup>nd</sup> dose	Antibody profiling (adaptive immunity i.e. anti- spike or anti-receptor binding protein, IgM, IgG, or IgA levels, self-antibodies) and T-cell responses (naive, effector, memory, SARS-CoV-2 spike– specific CD4+ T cells) in E group essentially indistinguishable from NE. Only noticeable difference in the T-cell signature was a higher frequency of PD-1–expressing bulk CD4+ T cells (P=0.02), likely reflecting variability in expansion after immunization but potentially also suggesting a higher level of exhaustion in this cell subset. E group had modest increase in cytokine production, with distinct cytokine profiles reminiscent of the profile seen in MIS-C, with significantly elevated levels of interleukin (IL)-8, IL-6, tumor necrosis factor-α, IL-10, interferon-γ, and IL-1β and lower IL-4 levels compared with NEV, with no notable differences in IL-5, IL- 12p70, or IL-22.	<ul> <li>mRNA vaccine—induced immune responses did not differ between individuals who developed myocarditis and individuals who did not. However, free spike antigen was detected in the blood of adolescents and young adults who developed post-mRNA vaccine myocarditis.</li> <li>These results suggest that postvaccine myocarditis is associated with normal adaptive and T-cell immunity but modest innate activation.</li> <li>Elevated levels of free spike protein in circulation, unbound by anti-spike antibodies, appear to correlate with cardiac troponin T levels and innate immune activation with cytokine release.</li> <li>Whether the circulating spike protein in the setting of mRNA vaccination was pathogenic is unclear. Spike protein appears to evade antibody recognition because the anti-spike antibodies that are generated are produced in adequate quantities with normal</li> </ul>		

## LIVING EVIDENCE SYNTHESIS: UPDATE #4 SUMMAI arche States arche

Author; Citation; Country	Methods Sample(s): E: exposed to myocarditis after vaccination NEV: no myocarditis after vaccine NE: other, as described		Findings	Authors' Conclusions				
			Complete blood count results: total leukocytes, specifically neutrophils, were significantly increased in E (P=0.007 and P=0.01, respectively), whereas platelet counts were decreased (P=0.03). Markedly elevated levels of full-length spike protein, unbound by antibodies in E, whereas no free spike was detected in NEV (P<0.0001). Free and antibody-bound spike, which was detectable only in E, remained detectable up to 3 weeks after vaccination, but no significant differences in antibody neutralization capacities were observed between groups.	functional and neutralization capacity. There is growing in vitro evidence that spike itself can stimulate cardiac pericytes dysfunction or inflame the endothelium, potentially by downregulating angiotensin-converting enzyme 2 expression, by impairing endothelial nitric oxide bioavailability, or by activating integrin-mediated inflammation with hyperpermeability of the endothelial cell layer. Thus, the spike antigen itself, which evades antibody recognition rather than invoking immune hyperactivation, may contribute to myocarditis in these individuals.				
Vago et al. Immunological response and temporal associations in myocarditis after COVID-19 vaccination using cardiac magnetic responace imaging: An amplified T-cell response at the heart of it? <i>Front Cardiovasc Med.</i> 9:961031. doi: 10.3389/fcvm.2022.9610 31 Hungary	After identification via CMR-based registry, routine laboratory testing and testing of humoral and cellular immune response to COVID-19 vaccination. Acute myocarditis was defined as per the modified Lake Louise criteria. Clinical and CMR follow-up was performed after 3–6 months in E and NE. Immune responses compared between E (mean of 109 and 86 days after the first and second doses) and NEV (matched by timing).	E: 16 (100% male; 22 ±7 years; 19% prior COVID-19) with CMR confirmed and clinical suspicion of acute myocarditis, frequently with predisposing factors such as immune-mediated disease (n=4) and previous myocarditis (n=2); 12 after mRNA vaccine; 81% after 2 <sup>nd</sup> dose, presented 4 ±2 days after vaccine. N=12 for immunologic response, NEV (no myocarditis but similar vaccination exposure; 91% previous COVID-19): 23, age- and sex-matched to E with similar doses and type of anti-SARS-CoV-2 vaccine and the time elapsed since their vaccination NE (myocarditis unrelated to COVID-19 or vaccination): 10 with CMR <2 weeks after the acute presentation	<ul> <li>E: white blood cell count, eosinophil count, and other markers remained in the normal range</li> <li>E vs NE: No difference in CMR metrics; marginal difference in T1 mapping.</li> <li>E vs NEV: 25% vs 91% previous COVID-19 but anti-NCP (IgG, IgM) testing showed no difference between the two groups.</li> <li>No difference in the humoral immune response i.e. Anti-SARS-CoV-2 modified nucleocapsid protein (NCP)-IgG, Anti-SARS-CoV-2 NCP-IgM, SARS-CoV-2 spike (S) protein receptor-binding domain (RBD) Ig, IgG or IgA.</li> <li>S1 IgG and IgA values negatively correlated with the time elapsed since the first vaccination.</li> <li>Markers of the humoral immune response showed higher values after the mRNA vaccine than after the vector vaccine.</li> <li>Increased T-cell response (p &lt; 0.01).</li> <li>No difference in the immune response of myocarditis patients with or without predisposing factors (but small sample).</li> <li>No correlation between the humoral</li> </ul>	An amplified cellular immune response was found in acute myocarditis cases occurring 4 days after COVID-19 vaccination. It seems that a T-cell response is sustained for several months after infection and appears to be more prolonged than the antibody response. It has also been suggested that the T-cell response to different COVID-19 vaccines differs among age groups.

			immune response (S Ig, SP1 IgG, SP1 IgA) and LVEF, whereas the T-cell response parameters showed a negative correlation with the marker of systolic function.	
Zahra et al. Neutralization of severe acute respiratory syndrome Coronavirus 2 Omicron and other variants in serum from children with vaccination-induced myocarditis. Clinical Infectious Diseases 2022;75(9):1645–8. https://doi.org/10.1093/ci d/ciac323 US	Serum samples for qualified SARS-CoV-2 pseudovirion neutralization assay using SARS-CoV-2 WA-1 strain and the 5 variants of concern (Alpha, Gamma, Beta, Delta, and Omicron) and 2 variants of interest (Lambda and Mu), and seroreactivity to SARS-CoV-2 recombinant spike- receptor binding domain from byWA-1 and Omicron	E: 13 (12 after 2 <sup>nd</sup> dose) acute (2–5 days post-mRNA vaccination) (100% male; 14.6 [13.8-15.7] years) and 10 post-acute (2-5 weeks after resolution of myocarditis) with no history of COVID-19 NEV: 10 healthy controls, 2-4 weeks after 2 <sup>nd</sup> dose of mRNA vaccine with no history of COVID-19	E: demonstrated neutralizing antibodies early (2– 5 days) post-vaccination against WA1/2020; post- acute, the neutralizing antibody response increased by 5-fold; similar trend for increase in neutralizing values of 2 to 8-fold from acute to post-acute time-point was observed across all SARS-CoV-2 variants; neutralization of Omicron was reduced by 31.8-fold compared with the vaccine homologous WA1/2020. End-point titer of serum IgG binding to WA1/2020. RBD was 13.7-fold higher than to Omicron NEV: highest neutralizing antibody response against vaccine homologous WA1/2020; response was reduced against SARS-CoV-2 variants ranging from 1.2-fold for Alpha to 3.3-fold against Beta. Neutralization titers against Omicron were reduced by 27.2-fold and 50% had no measurable neutralization titers. End-point titer of serum IgG binding to WA1/2020-RBD was 55-fold higher than to Omicron	Post-vaccination neutralization titers were significantly higher for children with vaccination- induced myocarditis (2–5 weeks post-vaccination) compared with healthy control children (2–4 weeks post-vaccination) against vaccine- homologous WA1/2020 as well as trended higher for Omicron (not statistically significant), possibly suggesting higher immunogenicity of mRNA vaccines in the vaccine-induced myocarditis children. Children with vaccination-induced myocarditis made a robust antibody response that trended higher than healthy children.

COVID-END

Appendix 1.

Supplementary Table 1. Eligibility criteria for a living evidence synthesis on myocarditis after mRNA COVID-19 vaccination.

Population/Problem	People of any age; data must be reported using age categories (e.g., 0- 4, 5-11, 12-17, 18-29, 30-39, $\geq$ 40 years).					
Intervention/Exposure	<ul> <li>KQ1: mRNA vaccines approved in Canada: BNT162b2 mRNA/PfizerBioNTech/Comirnaty, mRNA-1273/Moderna Spikevax (including bivalent versions and alternative manufacturers of same vaccine), by type of vaccine and dose.</li> <li>KQ2: Same as KQ1, plus potential risk/protective factors: pre-existing conditions [e.g. cardiac diseases, immunocompromise], previous SARS- CoV-2 infection (symptomatic or asymptomatic) or other viral infections, length of vaccine dosing interval.</li> <li>KQ3: Confirmed myocarditis or pericarditis after mRNA COVID-19 vaccination.</li> <li>KQ4: Confirmed myocarditis or pericarditis after mRNA COVID-19 vaccination.</li> <li>CQ1: Confirmed myocarditis or pericarditis after mRNA COVID-19 vaccination.</li> </ul>					
	Note: At least one dose of the vaccine needs to be with an mRNA vaccine; one or more other doses may be a non-mRNA vaccine.					
Control/Comparator	<ul> <li>KQ1: People previously vaccinated with mRNA COVID-19 vaccine but no longer at risk for outcome, previously vaccinated with other vaccines (i.e., controlling for confounders associated with vaccine uptake), or unvaccinated people; or no comparator.</li> <li>KQ2: People vaccinated with mRNA COVID-19 vaccine but without the risk/protective factor.</li> <li>KQ3: No comparator.</li> <li>KQ4: No comparator, but will include data on any comparisons with people vaccinated and not experiencing myocarditis or pericarditis.</li> <li>CQ1: People previously vaccinated with mRNA COVID-19 vaccine who did not experience myocarditis or pericardits; or no comparator.</li> </ul>					
Outcome	KQ1: Incidence rate/cumulative risk of confirmed myocarditis (including myopericarditis) or pericarditis by dose; subgroups based on time post-vaccination (0-7d vs 8-28d vs longer. Effect measures: incidence rate/cumulative risk (may be risk difference if accounting for background rate in control group); relative/absolute effects between groups (e.g., rate ratio or relative risk (RR) between vaccine types or doses). Will include rates of myocarditis or pericarditis (reported collectively) if there is no other data specific to myocarditis or pericarditis. Includes recurrence for people previously having mRNA vaccine-associated myocarditis or pericarditis. KQ2: Ratio measures of incidence/reported events by risk/protective factor (e.g., RR or odds ratios), adjusted for key confounders (e.g., previous COVID-19 illness and severity) when reported. KQ3: Characteristics of the patients (e.g., age, sex, pre-existing conditions [e.g., cardiac diseases] and infections [e.g., recent/past SARS-CoV-2 infection], race/ethnicity) and case presentation (e.g., timing/dose/type of vaccine, diagnostics, illness severity, treatments provided, short-term outcomes). KQ4: Any outcomes measured ≥12 weeks after onset of myocarditis or pericarditis (e.g., re-hospitalization, functional capacity, chest pain). CQ1: Data from investigations related to potential mechanisms (e.g., histology, experiments with viral spike glycoprotein of SARS-CoV-2 [encoded by mRNA vaccine]), gene panels, serology for innate and acquired immune system components, autoimmune antibodies).

NE = not estimated

NR = not reported

\*Indicates passive surveillance system with mandatory/legal reporting requirements for healthcare providers of adverse events after COVID-19 vaccines.

\*\*Number of administered vaccine doses from European Center for Disease Control (EDCD), up to end of Week 41 2021 (Oct 16 2021). Period of vaccine doses is shorter than event reporting to account for time period between receiving vaccine and experiencing the event of interest (i.e., individuals vaccinated on October 19 are unlikely to be reporting myocarditis as an AE on that same day) BNPV - Base Nationale de Pharmacovigilance is the French national spontaneous reporting database.

**HSA** – Health Science Authority of Singapore

**SAEFVIC** - Surveillance of Adverse Events Following Vaccination in the Community (SAEFVIC) is the state-wide vaccine safety service for the Australian state of Victoria. SAEFVIC comprises central reporting enhanced passive and active surveillance systems integrated with clinical services and has been operating since 2007.

**TGA** - The Therapeutic Goods Administration is the medicine and therapeutic regulatory agency of the Australian Government. As part of the Department of Health, the TGA regulates the quality, supply and advertising of medicines, pathology devices, medical devices, blood products and most other therapeutics.

VAERS – Vaccine Adverse Events Reporting System. Passive surveillance system for the United States, to which healthcare providers and patients can report adverse events from medical products, including vaccines. Providers are required to report to VAERS adverse events (including administration errors, serious adverse events, cases of multisystem inflammatory syndrome, and cases of COVID-19 that result in hospitalization or death) that occur after receipt of any COVID-19 vaccine. Limitations include possible bias in reporting, inconsistent data quality, and incomplete information; in addition, VAERS has no direct comparison group. The VAERS system was not designed to assess causality; therefore, VAERS data generally cannot be used to determine whether a causal association between an adverse event and a vaccine exists

BNPV - Base Nationale de Pharmacovigilance is the French national spontaneous reporting database.

COVaxON - Covid-19 Vaccinations Ontario is a central data repository for COVID-19 vaccine data and reporting in Ontario, administered by the Ontario Ministry of Health

EULAR COVAX- The European Alliance of Associations for Rheumatology Coronavirus Vaccine physician-reported registry. Data are entered voluntarily by rheumatologists or other members of the clinical rheumatology team; patients are eligible for inclusion if they registry have a pre-existing inflammatory/rheumatic and musculoskeletal disease or non-inflammatory rheumatic and musculoskeletal disease (NI-RMD) and have received one or more doses of any vaccine against SARS-CoV-2. Data are entered directly into an online data entry system or transferred from national registries (for Portugal). Patients with NI-RMDs are included as a control group.

- ISS/AIFA an active surveillance database, based on Regional health care claims, was set up by the Italian National Institute of Health (ISS) and the Italian Medicines Agency (AIFA) to provide real-world data on SARS-CoV-2 vaccine safety.
- NIMS The English National Immunisation (NIMS) Database of COVID-19 vaccination includes data on vaccine type, date and doses for all people vaccinated in England.
- **SAEFVIC** Surveillance of Adverse Events Following Vaccination in the Community (SAEFVIC) is the state-wide vaccine safety service for the Australian state of Victoria. SAEFVIC comprises central reporting enhanced passive and active surveillance systems integrated with clinical services and has been operating since 2007.
- SNDS the French administrative health care database covers around 99% of the French population, and includes anonymized data on socio-demographics, medical characteristics, ambulatory care, hospitalizations, diagnosis, drugs and procedures, mortality, and costs.
- VHA = Veteran's Health Administration is a nationalized healthcare service in the United States that provides healthcare and healthcare-adjacent services to Veterans through the administration and operation of healthcare facilities including inpatient, outpatient, and care home facilities.
- VAERS Vaccine Adverse Events Reporting System. Passive surveillance system for the United States, to which healthcare providers and patients can report adverse events from medical products, including vaccines. Providers are required to report to VAERS adverse events (including administration errors, serious adverse events, cases of multisystem inflammatory syndrome, and cases of COVID-19 that result in hospitalization or death) that occur after receipt of any COVID-19 vaccine. Limitations include possible bias in reporting, inconsistent data quality, and incomplete information; in addition, VAERS has no direct comparison group. The VAERS system was not designed to assess causality; therefore, VAERS data generally cannot be used to determine whether a causal association between an adverse event and a vaccine exists

#### Appendix 2. Evidence synthesis methods

#### Search strategy

We worked with an experienced medical information specialist (Becky Skidmore) to develop the search strategies. The initial search was peer-reviewed Oct 5, 2021, with slight modifications made in Dec 2021. Searches combine concepts for COVID-19, vaccines, and myocarditis/pericarditis/cardiovascular manifestations/adverse events/surveillance. The original search was limited to articles published since October 2020. We ran the searches for the first iteration of this review on October 6, 2021 and ran the first update on Jan 10, 2022. The second search update was run on April 11, 2022. We did not add limits for language, country or study design. After the first search, we removed the limits for human (not animal only) studies (to enable generation of a list of references to potentially relevant animal studies), as well as letters to the editor and commentaries. We added a limit to exclude case reports. We used Endnote for citation management.

#### Study Selection

In our original review we conducted 2 pilot rounds in Excel, using 200 records, with all team members involved in screening. Instead of redoing this step we provided an in-depth training session on the changes of scope to all review team members. We then conducted screening and selection in DistillerSR using structured forms. Title and abstract review used DistillerSR's machine learning tool (DAISY) which calculates the likelihood of inclusion for each unreviewed record based on those already screened and continually re-prioritizes records during screening. A single reviewer screened all titles/abstracts, and another reviewer verified exclusions for the first 50% records, where a large majority of relevant studies were located. For full text selection, a single reviewer reviewed all records, with exclusions verified by another reviewer and additional verification of included studies during data extraction.

#### Data Extraction

We extracted all data into structured tables and conducted a pilot exercise with 2 studies for each question. After the pilot, one reviewer extracted all data and a second reviewer verified it. Discrepancies were resolved by discussion or by a review lead. Specific equity-related populations of interest for study results were sex, age, and race/ethnicity.

For KQs 1 and 2, we distinguished between estimates of incidence compared with an unexposed group (excess incidence/risk differences) versus without a control. We extracted data on incident rates per person-years and per doses of vaccine/people vaccinated (dose 2). We extracted data on any stratified or subgroup analyses based on age, sex, different vaccine types, and different risk intervals. Effect measures included: incidence rate/cumulative risk (including excess risk [risk difference] when using a control group) and relative and absolute effects between groups (e.g., incidence rate ratio (IRR) or risk difference), adjusted for key confounders (i.e., age, sex, infection status, cardiac and immunodeficiency/autoimmune conditions) when reported. When both incidence rates and excess incidence were reported, we prioritized the latter for synthesis.

#### **Risk of Bias Assessment**

One review lead and all other reviewers piloted each risk of bias tool with 10% (or 2 whichever is higher) papers. Assessments were then completed by one reviewer and verified by another. Discrepancies were resolved by discussion or by a review lead. We used the JBI checklist for cohort studies, with focus on valid and reliable outcome ascertainment and, for KQ2, accounting for key confounders including pre-existing health conditions and prior COVID-19 exposure (including during long-term follow-up). The findings of the risk of bias assessments were used when undertaking Grading of Recommendations, Assessment, Development and Evaluation (GRADE) assessments of the certainty of the evidence.

We did not assess risk of bias for studies included in KQs 3 or 4 or for CQ1.

#### Synthesis

We analyzed data on myocarditis (including myopericarditis) and pericarditis separately, when able. Data are summarized descriptively and the results were contextualized for the Canadian context. For KQs 1 and 2, we did not pool results from the included studies due to heterogeneity in dosing and risk intervals, and case ascertainment methods. We tabulated all results and compared and contrasted findings between studies based on the major differentiating population, vaccine and methodologic variables. We reached consensus on a best estimate of the incidence or a range. Based on clinical input we developed primary age categories (5-11y, 12-17y,

Public Health

18-29y, 30-39y,  $\geq$ 40y) to report on, when possible. If a study contributed more than one result within these (e.g., 20-24v and 25-29v, results for each mRNA vaccine) we took the weighted average of the incident rates. When a study reported an incidence rate (or data to calculate this) and an IRR compared with a control/background rate, but not the difference in incidence (excess incidence over background rate), we calculated the excess incidence (i.e., crude incidence – [crude incidence/IRR]). Summary of findings tables were developed with GRADE applied to results for KQs 1 and 2. Descriptive tables were created for KQs 3 and 4, and CQ1.

For KQs 1 and 2, we assessed the certainty for each of our conclusion statements using GRADE. For KQ1, observational studies started at Low certainty; for KQ2, studies started at High certainty. We rated down based on serious concerns about risk of bias, inconsistency, indirectness, imprecision, and/or reporting biases. For KQ1, we considered incidence rates <20 per million to be "little-to-none"; for KQ2, associations ≥1.5 (OR/RR) were considered clinically relevant (i.e., OR <1.5 shows "little-to-no association"). For KQ1, we rated down for indirectness for comparisons across both sexes, due to the large heterogeneity in incidence rates across ages (for males) and sexes. We considered rating up for observational studies due to large incidence rates when no other major limitations were evident, as recommended in the GRADE guidance.(Guyatt et al, https://doi.org/10.1016/i.jclinepi.2011.06.004), or when incidence rates were zero or near zero across multiple studies with large sample sizes.
